#### 9.1、Experiment Description

#### 9.2、Experimental goal

#### 9.3、Experimental steps

#### 9.4、Experimental effect

#### 9.5、Experiment summary

## 9.1、Experiment Description

**Note: This experiment is an expansion experiment and needs to be used with other external devices. The car chassis and ROS expansion board used here are not part of the K210 development board kit, so the effect of this experiment is for reference only. If there is no corresponding device, it cannot be used. Use this example code directly.**

The ROS expansion board needs to flash the firmware in advance: ROS-CAR.hex

The corresponding interface for connecting the gimbal servo to the ROS expansion board is:

S1 is connected to the X-axis servo, and S2 is connected to the Y-axis servo. The yellow wire is the signal, the red wire is VCC, and the black wire is GND.

The line sequence of the connection between the K210 development board and the ROS expansion board is shown in the figure below:

The white wire is connected to GND, the yellow wire is connected to VCC, the black wire is connected to SCL, and the red wire is connected to SDA.

It should be noted here that the logo in the diagram is the I2C line sequence logo, but the K210 uses serial port communication. Since the burned ROS-CAR.hex file has changed this interface to a serial port signal, the actual ROS expansion board The corresponding relationship of the interface is: SCL is actually TX, and SDA is actually RX.

## 9.2、 Experimental goal

This lesson mainly learns the function of K210 development board and car chassis for visual line inspection.

The reference code path for this experiment is: 06-export\tracking\_face.py

## 9.3、 Experimental steps

1. ROS expansion board flash firmware: ROS-CAR.hex
2. Insert the RGB light bar into the RGB light interface of the ROS expansion board.
3. Please download the trolley driver library and PID control library in the 06-export\library directory to the root directory of the memory card in advance.
4. Open CanMV IDE, open the tracking\_face.py code and download it to the K210 development board.

5. Connect the K210 development board to the ROS expansion board through a 4PIN cable.
6. Put the gimbal on a white or black background, and then turn on the power of the ROS expansion board.
7. When the face enters the acquisition range of the camera of the K210 development board, the K210 development board will frame the face, and the gimbal will track the face.

## 9.4、 Experimental effect

After the system initialization is completed, the camera of the K210 development board will detect whether there is a face in the screen in real time. If there is a face in the screen, modify the angle of the gimbal servo to keep the face in the middle of the screen as much as possible, and the camera will track the rotation of the face.

If the tracking response is too fast or too slow, you can properly modify the PID parameters in the program.

```
PIDx = (50, 0, 15)
PIDy = (50, 0, 10)
SCALE = 1000.0

✓ PID_x = PID(
    160,
    PIDx[0] / 1.0 / (SCALE),
    PIDx[1] / 1.0 / (SCALE),
    PIDx[2] / 1.0 / (SCALE))

✓ PID_y = PID(
    120,
    PIDy[0] / 1.0 / (SCALE),
    PIDy[1] / 1.0 / (SCALE),
    PIDy[2] / 1.0 / (SCALE))
```

## 9.5、 Experiment summary

The gimbal tracking face game is developed based on the face detection function. The K210 development board camera detects the position coordinates of the face, and calculates the position where the gimbal needs to move through the PID algorithm, so that the gimbal can track the face in front of the camera. . Due to frame rate and recognition limitations, face movement should not be too fast, otherwise the gimbal may not be able to keep up with the response.
